# 1. Introduction

Adv. Macro: Heterogenous Agent Models

Jeppe Druedahl & Raphaël Huleux

2025

Introduction

#### Introduction

- Teachers: Jeppe Druedahl & Raphaël Huleux
- Central economic questions:
  - What role does heterogeneity play for understanding consumption-saving dynamics in partial equilibrium? (incl. single-agent problems)
  - 2. What role does heterogeneity play for understanding secular trends in general equilibrium?
  - 3. What explains the level and dynamics of heterogeneity/inequality?
  - 4. What role does heterogeneity play for understanding business-cycle fluctuations in general equilibrium?
- Central technical method: Programming in Python
   Prerequisite: Intro. to Programming and Numerical Analysis
   Complicated: Close to the research frontier

# Macroeconomic Models with Heterogeneous Agents

#### Model components:

- 1. Optimizing individual agents (households + firms)
- 2. Idiosyncratic and aggregate risk
- 3. Information flows (who knows what when  $\Rightarrow$  often everything)
- 4. Market clearing (Walras vs. search-and-match)

#### Insurance/markets:

 $Complete 
ightarrow idiosyncratic risk insured away \sim representative agent Incomplete 
ightarrow agents need to self-insure$ 

#### Heterogeneity:

Ex ante in preferences, abilities etc.
Ex post after realization of idiosyncratic shocks

- HANC: Heterogeneous Agent *Neo-Classical* model (Aiyagari-Bewley-Hugget-Imrohoroglu or Standard Incomplete Markets model)
- HANK: Heterogeneous Agent New Keynesian model (i.e. include price and wage setting frictions)

# History of heterogeneous agent macro

- 1. Heathcote et al. (2009), »Quantitative Macroeconomics with Heterogeneous Households«
- 2. Kaplan and Violante (2018), »Microeconomic Heterogeneity and Macroeconomic Shocks«
- 3. Cherrier et al. (2023), »Household Heterogeneity in Macroeconomic Models: A Historical Perspective«
- 4. Auclert et. al. (2025), »Fiscal and Monetary Policy with Heterogeneous Agents«

**Structure** 

# Teaching method

- Lectures: Tuesday 12-15
  - ~2 hours of »normal« lecture
  - ~1 hour of code review and problem solving (no exercise classes)

#### Content:

- 1. Explanation of computational methods
- 2. Exposition of central stylized results
- 3. Code examples for central methods and mechanisms
- 4. Discussion of research papers

#### Material:

Web: sites.google.com/view/numeconcph-advmacrohet/ Git: github.com/numeconcopenhagen/adv-macro-het

#### Code:

- 1. We provide code you will build upon
- 2. Based on the GEModelTools package

# **Assignments and exam**

- Individual assignments (hand-in on Absalon)
  - 1. Assignment I

Deadline: 23rd of October (must be approved before exam)

2. Assignment II

Deadline: 20th of November (must be approved before exam)

3. **Assignment III** with essay on a relevant model extension of own choice and a simple implementation

Deadline for proposal: 10th of December

Deadline for peer feedback: 14th of December (exam requirement)

- All feedback can be used to improve assignments before the exam
- Exam:
  - 1. Hand-in 3×assignments
  - 2. **36 hour take-home:** Programming of new extension
    - + analysis of model + interpretation of results

## **Python**

- Assumed knowledge: From Introduction to Programming and Numerical Analysis you are assumed to know the basics of
  - 1.1 Python
  - 1.2 VSCode
  - 1.3 git
- 2. Updated Python: Install (or re-install) newest Anaconda
- 3. Packages: pip install quantecon, EconModel, consav
- 4. GEMoodel tools:
  - 4.1 Clone the GEModelTools repository
  - 4.2 Locate repository in command prompt
  - $4.3 \ \mathsf{Run} \ \mathsf{pip} \ \mathsf{install} \ \mathsf{-e} \ .$

# Course plan

- Lecture 1-2: Consumption-saving models
- Lecture 3-6: General equilibrium model (stationary equilibrium + transition path)
- Lecture 7: Wealth inequality
- Lecture 8-13: HANK
- Lecture 14: Exam and perspectives

**Learning goals** 

# Knowledge

- 1. Account for, formulate and interpret precautionary saving models
- 2. Account for stochastic and non-stochastic simulation methods
- Account for, formulate and interpret general equilibrium models with ex ante and ex post heterogeneity, idiosyncratic and aggregate risk, and with and without pricing frictions
- 4. Discuss the difference between the stationary equilibrium, the transition path and the dynamic equilibrium
- Discuss the relationship between various equilibrium concepts and their solution methods
- Identify and account for methods for analyzing the dynamic distributional effects of long-run policy (e.g. taxation and social security) and short-run policy (e.g. monetary and fiscal policy)

## Skills

- 1. Solve precautionary saving problems with dynamic programming and simulate behavior with stochastic and non-stochastic techniques
- 2. Solve general equilibrium models with ex ante and ex post heterogeneity, idiosyncratic and aggregate risk, and with and without pricing frictions (stationary equilibrium, transition path, dynamic equilibrium)
- 3. Analyze dynamics of income and wealth inequality
- 4. Analyze transitional and permanent structural changes (e.g. inequality trends and the long-run decline in the interest rate)
- Analyze the dynamic distributional effects of long-run policy (e.g. taxation and social security) and short-run policy (e.g. monetary and fiscal policy)

# Competencies

- Independently formulate, discuss and assess research on both the causes and effects of heterogeneity and risk for both long-run and short-run outcomes
- 2. Discuss and assess the importance of how heterogeneity and risk is modeled for questions about both long-run and short-run dynamics

**Programming in Python** 

#### **Classes**

- A class defines the type of an object
  - .attribute, state
  - .method(), action (incl. changing self)
- Inheritance (of methods) (class Child(Parent))

```
class Parent:
2
       def __init__(self, value): self.value = value
3
       def double(self): return self.value * 2
4
   class Child(Parent):
6
       def half(self): return self.value / 2
 7
  child = Child(10)
  print(child.value) # 10
10 print(child.double()) # 20
11 print(child.half()) # 5.0
```

#### References

- Variables are references to an instance of an object
- = assigns a reference (not a copy!)

**Question:** What does a end up as? What if a = [1,2,3]?

```
1  a = np.array([1,2,3])
2  b = a
3  c = a[1:] # slicing
4  b[0] = 3 # indexing
5  c[0] = 3
```

# Types and in-place operations

- Atomic types: int, float, str, bool, etc.
- Containers list, tuple, dict, set, np.array, etc.
- Mutables (e.g. list, np.array) can change in-place
  - 1. In-place operators (+=, -= etc.)
  - 2. Slicing: x[:] = x + y
- Immutables (e.g. atomic types and tuples) can never change

Questions: What does y end up as?

```
1 x = np.array([1,2,3])

y = x

3 x += 1

4 x[:] = x + 1

5 x = x + 1
```

# **Functions and scope**

- Functions are objects (can e.g. be arguments in functions)
  Unlike in math:
  - 1. Can change its arguments (side-effects)
  - 2. Can call itself (recursion)
- Decorators change function behavior (e.g. @numba.njit)
- Variables can both be local scope (good) or global scope (bad)

#### Questions: What is the output?

```
1  a = 1
2  def f(x):
3    return x+a
4  print(f(1))
5  a = 2
6  print(f(1))
```

# Conditionals and loops

- **Comparison** (==, !=, <, <=, not, and, or etc.)
- Conditionals (if, elif, else)
- Loops (for, while, continue, break)
- Convergence (tolerance in optimizer or root-finder/equation-solver)

Questions: How could this be implemented with a while loop?

```
1  x = x0
2  for i in range(n):
3     y = evaluate(x)
4     if check(y): break
5     x = update(x,y)
6  else:
7     raise ValueError('did not converge')
```

## Decimal numbers are not exact

- Never use exactness for decimal numbers
  - Order of computation matter
  - Best with numbers are around 1 (underflow and overflow)
- Division, exp, log etc. are (costly) approximations
- Function approximation and interpolation often needed

Questions: Which are True and which are False?

```
print(0.1 + 0.2 == 0.3)
print(0.5 + 0.5 == 1.0)
print(np.isclose(0.1+0.2,0.3))
print(np.isclose(1e-200*1e200*1e200*1e-200,1.0))
print(np.isinf(1e-200*(1e200*1e200)*1e-200))
print(np.isclose(1e200*(1e-200*1e-200)*1e200,0.0))
```

#### Pseudo random numbers

- Only one seed (randomness not assured across seeds)
- State of random number generator can be reset
- Monte Carlo simulation and integration
  - 1. Static alternative: Use quadrature rules
  - 2. Dynamic alternative: Discretize and derive transition matrix

### Questions: What is z equal to?

```
rng = np.random.default_rng(123)
s = rng.bit_generator.state
x = rng.normal(size=5)
y = rng.normal(size=5)
rng.bit_generator.state = s
z = rng.normal(size=5)
```

# Documentation and debugging

- No code is self-explanatory (for others, incl. future you)
- Write documentation (use github-copilot)
  - 1. The comments explain humans what the code does.
  - 2. The code makes the computer do what the comments say
- Important design patterns:
  - 1. Use namespaces (be aware of scope) and meaningful names
  - 2. No repetition of code-lines  $\Rightarrow$  single-purpose functions/methods
  - 3. Use assert (also print and plot intermediate results)
  - 4. Use try-except
- Run from top to bottom (make <u>shortcut</u>)

Replication: datacodestandard.org

- Debugging (see 02. Debugging.ipynb)
  - 1. Errors are (almost) always simple
  - 2. Go through code step-by-step (manually or debugger)

## Numba and EconModelClass

- Numba: Faster code (03. Numba.ipynb)
- EconModel (04. EconModelClass.ipynb)
  - 1. Make it easy to write well-structured code
  - 2. Provide standard functionality for copying, saving and loading
  - 3. Provide an easy interface to call numba JIT compilled functions
  - 4. Provide an easy interface to call C++ functions (not relevant in this course)

# Consumption-Saving

# **Consumption-saving**

We start on the slides for lecture 2
